# Part 1.

# Introduction

## What is Docker (1/3)

*"Docker is an open platform for developers and sysadmins to build, ship, and run distributed applications."*

*Consisting of Docker Engine, a portable, lightweight runtime and packaging tool, and Docker Hub, a cloud service for sharing applications and automating workflows, Docker enables apps to be quickly assembled from components and eliminates the friction between development, QA, and production environments. As a result, IT can ship faster and run the same app, unchanged, on laptops, data center VMs, and any cloud."*

source: <https://www.docker.com/whatisdocker/>

## What is Docker (2/3)

- a container manager
  - lightweight virtualisation  
*(host and guest systems share the same kernel)*
  - based on linux namespaces and cgroups
- massively copy-on-write
  - immutable images
  - instant deployment
  - suitable for micro-services (one process, one container)

→ immutable architecture

## What is Docker (3/3)

- a build system
  - images may be build from sources
  - using a simple DSL (`Dockerfile`)
- a set of REST APIs
  - Remote API (control the docker engine)
  - Registry API (publish/download images)
  - Swarm API (manage a clustered of docker machines)

# How Docker helps?

- **normalisation:** same environment (container image) for
  - development
  - jobs on the computing grid
  - continuous integration
  - peer review
  - demonstrations, tutorials
  - technology transfer
- **archival** (*ever tried to reuse old codes*)
  - source → Dockerfile = recipe to rebuild the env from scratch
  - binary → docker image = immutable snapshot of the software with its runtime environment
    - can be rerun it at any time later

## In practice

A docker image is an immutable snapshot of the filesystem

A docker container is

- a temporary file system
  - layered over an immutable fs (docker image)
  - fully writable (copy-on-write<sup>1</sup>)
  - dropped at container's end of life (unless a `commit` is made)
- a network stack
  - with its own private address (*by default in 172.17.x.x*)
- a process group
  - one main process launched inside the container
  - all sub-process SIGKILLed when the main process exits

---

<sup>1</sup>several possible methods: overlayfs (default), btrfs, lvm, zfs, aufs

# Installation

<https://docs.docker.com/installation/>

Native installation:

- requires linux kernel >3.8

Docker Machine:

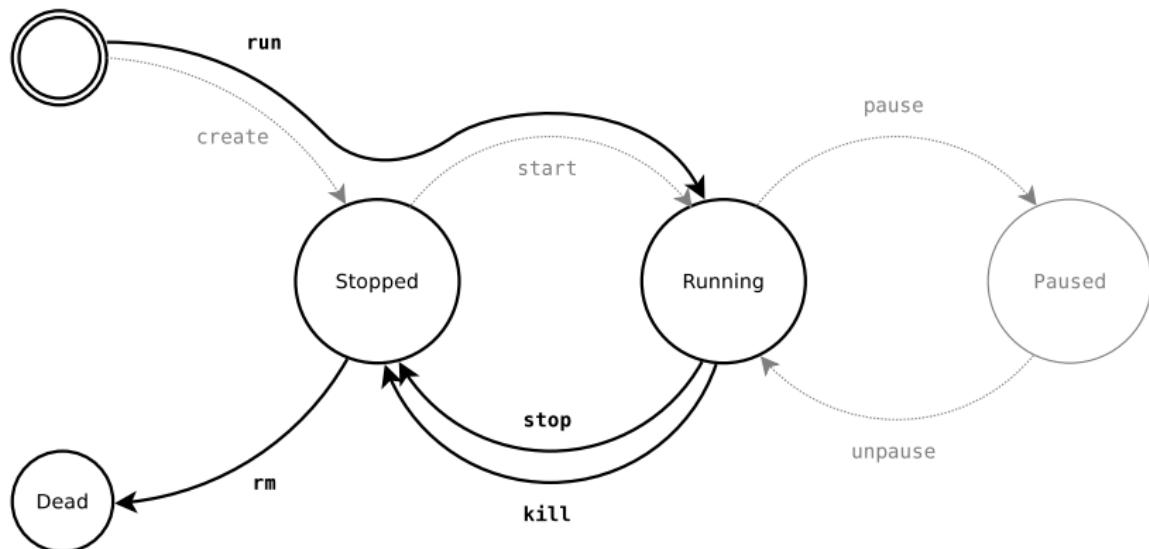

- a command for provisionning and managing docker nodes deployed:
  - in a local VM (virtualbox)
  - remotely (many cloud API supported)

# Part 2.

# Managing containers

- create/start/stop/remove containers
- inspect containers
- interact, commit new images

# Lifecycle of a docker container

# Container management commands

command	description
<code>docker create image [ command ]</code> <code>docker run image [ command ]</code>	create the container = <code>create + start</code>
<code>docker start container...</code>	start the container
<code>docker stop container...</code>	graceful <sup>2</sup> stop
<code>docker kill container...</code>	kill (SIGKILL) the container
<code>docker restart container...</code>	= <code>stop + start</code>
<code>docker pause container...</code>	suspend the container
<code>docker unpause container...</code>	resume the container
<code>docker rm [ -f<sup>3</sup> ] container...</code>	destroy the container

<sup>2</sup>send SIGTERM to the main process + SIGKILL 10 seconds later

<sup>3</sup>-f allows removing running containers (= `docker kill + docker rm`)

## Notes about the container lifecycle

- the root filesystem is created in `create` and dropped in `rm`  
*(it is persistent across `stop/start`)*
- the container configuration is mostly static  
*(it is set in the `create`<sup>4</sup> command)*
- the other commands are more basic

---

<sup>4</sup>or `run`

Usage: docker create [OPTIONS] IMAGE [COMMAND] [ARG...]

Create a new container

```
-a, --attach=[]          Attach to STDIN, STDOUT or STDERR
--add-host=[]           Add a custom host-to-IP mapping (host:ip)
--blkio-weight=0        Block IO (relative weight), between 10 and 1000
--cpu-shares=0          CPU share (relative weight)
--cap-add=[]            Add Linux capabilities
--cap-drop=[]           Drop Linux capabilities
--cgroup-parent=        Optional parent cgroup for the container
--cidfile=              Write the container ID to the file
--cpu-period=0          Limit CPU CFS (Completely Fair Scheduler) period
--cpu-quota=0           Limit CPU CFS (Completely Fair Scheduler) quota
--cpuset-cpus=          CPUs in which to allow execution (0-3, 0,1)
--cpusets-mems=         MEMs in which to allow execution (0-3, 0,1)
--device=[]             Add a host device to the container
--disable-content-trust=true
--dns=[]                Skip image verification
--dns-opt=[]             Set custom DNS servers
--dns-search=[]          Set custom DNS search domains
-e, --env=[]             Set environment variables
--entrypoint=            Overwrite the default ENTRYPOINT of the image
--env-file=[]            Read in a file of environment variables
--expose=[]              Expose a port or a range of ports
--group-add=[]           Add additional groups to join
-h, --hostname=          Container host name
--help=false             Print usage
-i, --interactive=false
--ipc=                  Kernel memory limit
--kernel-memory=
-l, --label=label[]     Set meta data on a container
--label-file=[]          Read in a line delimited file of labels
--links[]                Add link to another container
--log-driver=             Logging driver for container
--log-opt=[]              Log driver options
--lxc-conf[]              Add custom lxc options
-m, --memory=             Memory limit
--mac-address=            Container MAC address (e.g. 92:00:c6:0a:29:33)
--memory-reservation=
--memory-swap=            Memory soft limit
--memory-swapiness=-1   Total memory (memory + swap), '-1' to disable swap
--net=default             Tuning container memory swapiness (0 to 100)
--name=                  Assign a name to the container
--net=default             Set the Network for the container
--oom-kill-disable=false
--oomevictimize=false
-p, --publish-all=false
-p, --publish=[]          Publish all exposed ports to random ports
--pid=                  Publish a container's port(s) to the host
--privileged=false       PID namespace to use
--read-only=false        Give extended privileges to this container
--read-only=false        Mount the container's root filesystem as read only
--restart=none           Restart policy to apply when a container exits
--security-opt=[]         Security Options
--stop-signal=SIGHTERM
-t, --tty=false           Signal to stop a container, SIGHTERM by default
-u, --user=               Allocate a pseudo-TTY
-u, --user=username      Username or UID (format: <name>/uid[:<group>/gid>])
--ulimit[]                Ulimit options
--uts=                   UTS namespace to use
-v, --volume=[:]          Bind mount a volume
--volume-driver=          Optional volume driver for the container
--volume-from=[:]         Mount volumes from the specified container(s)
-w, --workdir=            Working directory inside the container
```

Usage: docker start [OPTIONS] CONTAINER [CONTAINER...]

Start one or more stopped containers

```
-a, --attach=false        Attach STDOUT/STDERR and forward signals
--help=false              Print usage
-i, --interactive=false  Attach container's STDIN
```

Usage: docker stop [OPTIONS] CONTAINER [CONTAINER...]

Stop a running container.  
Sending SIGTERM and then SIGKILL after a grace period

```
--help=false              Print usage
-t, --time=10             Seconds to wait for stop before killing it
```

Usage: docker restart [OPTIONS] CONTAINER [CONTAINER...]

Restart a container

```
--help=false              Print usage
-t, --time=10             Seconds to wait for stop before killing the container
```

Usage: docker kill [OPTIONS] CONTAINER [CONTAINER...]

Kill a running container

```
--help=false              Print usage
-s, --signal=SIGKILL     Signal to send to the container
```

Usage: docker rm [OPTIONS] CONTAINER [CONTAINER...]

Remove one or more containers

```
-f, --force=false         Force the removal of a running container (uses SIGKILL)
--help=false              Print usage
-l, --link=false          Remove the specified link
-v, --volumes=false       Remove the volumes associated with the container
```

Usage: docker pause [OPTIONS] CONTAINER [CONTAINER...]

Pause all processes within a container

```
--help=false              Print usage
```

## docker run — Run a container

<https://docs.docker.com/reference/run/>

```
docker run [ options ] image [ arg0 arg1... ]
```

→ create a container and start it

- the container filesystem is initialised from image *image*
- *arg0..argN* is the command run inside the container (as PID 1)

```
$ docker run debian /bin/hostname
f0d0720bd373
$ docker run debian date +%H:%M:%S
17:10:13
$ docker run debian true ; echo $?
0
$ docker run debian false ; echo $?
1
```

# docker run — Foreground mode vs. Detached mode

- Foreground mode is the default
  - *stdout* and *stderr* are redirected to the terminal
  - `docker run` propagates the exit code of the main process
- With `-d`, the container is run in detached mode:
  - displays the ID of the container
  - returns immediately

```
$ docker run debian date
Tue Jan 20 17:32:07 UTC 2015
$ docker run -d debian date
4cbdefb3d3e1331ccf7783b32b47774fefca426e03a2005d69549f3ff06b9306
$ docker logs 4cbdef
Tue Jan 20 17:32:16 UTC 2015
```

## docker run — TTY allocation

Use **-t** to allocate a pseudo-terminal for the container

→ without a tty

```
$ docker run debian ls
bin
boot
dev
...
$ docker run debian bash
$
```

→ with a tty (**-t**)

```
$ docker run -t debian ls
bin dev home lib64 mnt proc run selinux sys usr
boot etc lib media opt root sbin srv tmp var
$ docker run -t debian bash
root@10d90c09d9ac:/#
```

## docker run — interactive mode

- By default containers are non-interactive
  - *stdin* is closed immediately
  - terminal signals are not forwarded<sup>5</sup>

```
$ docker run -t debian bash
root@6fecc2e8ab22:/# date
^C
$
```

- With **-i** the container runs interactively
  - *stdin* is usable
  - terminal signals are forwarded to the container

```
$ docker run -t -i debian bash
root@78ff08f46cdb:/# date
Tue Jan 20 17:52:01 UTC 2015
root@78ff08f46cdb:/# ^C
root@78ff08f46cdb:/#
```

---

<sup>5</sup>^C only detaches the terminal, the container keeps running in background

## docker run — override defaults (1/2)

### user (-u)

```
$ docker run debian whoami
root
$ docker run -u nobody debian whoami
nobody
```

### working directory (-w)

```
$ docker run debian pwd
/
$ docker run -w /opt debian pwd
/opt
```

## docker run — override defaults (2/2)

### environment variables (**-e**)

```
$ docker run debian sh -c 'echo $FOO $BAR'  
  
$ docker run -e FOO=foo -e BAR=bar debian sh -c 'echo $FOO $BAR'  
foo bar
```

### hostname (**-h**)

```
$ docker run debian hostname  
830e47237187  
$ docker run -h my-nice-container debian hostname  
my-nice-hostname
```

# docker run — set the container name

--name assigns a name for the container

(by default a random name is generated → adjective\_name)

```
$ docker run -d -t debian
da005df0d3aca345323e373e1239216434c05d01699b048c5ff277dd691ad535
$ docker run -d -t --name blahblah debian
0bd3cb464ff68eaf9fc43f0241911eb207fefd9c1341a0850e8804b7445ccd21
$ docker ps
CONTAINER ID   IMAGE      COMMAND      CREATED          ..   NAMES
0bd3cb464ff6   debian:7.5  "/bin/bash"   6 seconds ago    blahblah
da005df0d3ac   debian:7.5  "/bin/bash"   About a minute ago   drunk_darwin
$ docker stop blahblah drunk_darwin
```

**Note:** Names must be unique

```
$ docker run --name blahblah debian true
2015/01/20 19:31:21 Error response from daemon: Conflict, The name blahblah is already assigned
to 0bd3cb464ff6. You have to delete (or rename) that container to be able to assign blahblah to a
container again.
```

## docker run — autoremove

By default the container still exists after command exit

```
$ docker run --name date-ctr debian date
Tue Jan 20 18:38:21 UTC 2015
$ docker start date-ctr
date-ctr
$ docker logs date-ctr
Tue Jan 20 18:38:21 UTC 2015
Tue Jan 20 18:38:29 UTC 2015
$ docker rm date-ctr
date-ctr
$ docker start date-ctr
Error response from daemon: No such container: date-ctr
2015/01/20 19:39:27 Error: failed to start one or more containers
```

With `--rm` the container is automatically removed after exit

```
$ docker run --rm --name date-ctr debian date
Tue Jan 20 18:41:49 UTC 2015
$ docker rm date-ctr
Error response from daemon: No such container: date-ctr
2015/01/20 19:41:53 Error: failed to remove one or more containers
```

## Common rm idioms

Launch an throwaway container for debugging/testing purpose

```
$ docker run --rm -t -i debian
root@4b71c9a39326:/#
```

Remove all zombie containers

```
$ docker ps -a
CONTAINER ID  IMAGE      COMMAND      CREATED      STATUS
2b291251a415  debian:7.5  "hostname"  About a minute ago  Exited (0) About a mi
6d36a2f07e18  debian:7.5  "false"     2 minutes ago    Exited (1) 2 minutes
0f563f110328  debian:7.5  "true"      2 minutes ago    Exited (0) 2 minutes
4b57d0327a20  debian:7.5  "uname -a"  5 minutes ago   Exited (0) 5 minutes
$ docker ps -aq | xargs docker rm
2b291251a415
6d36a2f07e18
0f563f110328
4b57d0327a20
```

# Inspecting the container

command	description
<code>docker ps</code>	list running containers
<code>docker ps -a</code>	list all containers
<code>docker logs [ -f<sup>6</sup> ] container</code>	show the container output ( <i>stdout+stderr</i> )
<code>docker top container [ ps options ]</code>	list the processes running inside the containers
<code>docker diff container</code>	show the differences with the image (modified files)
<code>docker inspect container...</code>	show low-level infos (in json format)

<sup>6</sup>with `-f`, `docker logs` follows the output (à la `tail -f`)

# Interacting with the container

command	description
<code>docker attach container</code>	attach to a running container (stdin/stdout/stderr)
<code>docker cp container:path hostpath - docker cp hostpath - container:path</code>	copy files from the container copy files into the container
<code>docker export container</code>	export the content of the container (tar archive)
<code>docker exec container args...</code>	run a command in an existing container ( <b>useful</b> for debugging)
<code>docker wait container</code>	wait until the container terminates and return the exit code
<code>docker commit container image</code>	commit a new docker image (snapshot of the container)

## docker commit example

```
$ docker run --name my-container -t -i debian
root@3b397d383faf:/# cat >> /etc/bash.bashrc <<EOF
> echo 'hello!'
> EOF
root@3b397d383faf:/# exit
$ docker start --attach my-container
my-container
hello!
root@3b397d383faf:/# exit
$ docker diff my-container
C /etc
C /etc/bash.bashrc
A /.bash_history
C /tmp
$ docker commit my-container hello
a57e91bc3b0f5f72641f19cab85a7f3f860a1e5e9629439007c39fd76f37c5dd
$ docker rm my-container
my-container
$ docker run --rm -t -i hello
hello!
root@386ed3934b44:/# exit
$ docker images -t
511136ea3c5a Virtual Size: 0 B
af6bd397692 Virtual Size: 115 MB
667250f9a437 Virtual Size: 115 MB Tags: debian:wheezy, debian:latest
a57e91bc3b0f Virtual Size: 115 MB Tags: hello:latest
```

# Part 3.

# Inputs/Outputs

- External volumes (persistent data)
- Devices
- Links
- Publishing ports (NAT)

## docker run — mount external volumes

```
docker run -v /hostpath:/containerpath[:ro] ...
```

`-v` mounts the location `/hostpath` from the host filesystem at the location `/containerpath` inside the container

With the “`:ro`” suffix, the mount is read-only

Purposes:

- store persistent data outside the container
- provide inputs: data, config files, ... (read-only mode)
- inter-process communication (unix sockets, named pipes)

# mount examples (1/2)

## Persistent data

```
$ docker run --rm -t -i -v /tmp/persistent:/persistent debian
root@0aeedfeb7bf9:/# echo "blahblah" >/persistent/foo
root@0aeedfeb7bf9:/# exit
$ cat /tmp/persistent/foo
blahblah
$ docker run --rm -t -i -v /tmp/persistent:/persistent debian
root@6c8ed008c041:/# cat /persistent/foo
blahblah
```

## Inputs (read-only volume)

```
$ mkdir /tmp/inputs
$ echo hello > /tmp/inputs/bar
$ docker run --rm -t -i -v /tmp/inputs:/inputs:ro debian
root@05168a0eb322:/# cat /inputs/bar
hello
root@05168a0eb322:/# touch /inputs/foo
touch: cannot touch `/inputs/foo': Read-only file system
```

## mount examples (2/2)

### Named pipe

```
$ mkfifo /tmp/fifo
$ docker run -d -v /tmp/fifo:/fifo debian sh -c 'echo blah blah> /fifo'
ff0e44c25e10d516ce947eae9168060ee25c2a906f62d63d9c26a154b6415939
$ cat /tmp/fifo
blah blah
```

### Unix socket

```
$ docker run --rm -t -i -v /dev/log:/dev/log debian
root@56ec518d3d4e:/# logger blah blah blah
root@56ec518d3d4e:/# exit
$ sudo tail /var/log/messages | grep logger
Jan 21 08:07:59 halfloat logger: blah blah blah
```

## docker run — grant access to a device

By default devices are not usable inside the container

```
$ docker run --rm debian fdisk -l /dev/sda
root@dcba37b0c0bd:/# fdisk -l /dev/sda
fdisk: cannot open /dev/sda: No such file or directory

$ docker run --rm debian sh -c 'mknod /dev/sda b 8 0 && fdisk -l /dev/sda'
fdisk: cannot open /dev/sda: Operation not permitted

$ docker run --rm -v /dev/sda:/dev/sda debian fdisk -l /dev/sda
fdisk: cannot open /dev/sda: Operation not permitted
```

They can be whitelisted with `--device`

```
docker run --device /hostpath[:/containerpath] ...
```

```
$ docker run --rm --device /dev/sda debian fdisk -l /dev/sda
Disk /dev/sda: 250.1 GB, 250059350016 bytes
...
```

## docker run — inter-container links (legacy links<sup>7</sup>)

Containers cannot be assigned a static IP address (by design)  
→ service discovery is a must

Docker “links” are the most basic way to discover a service

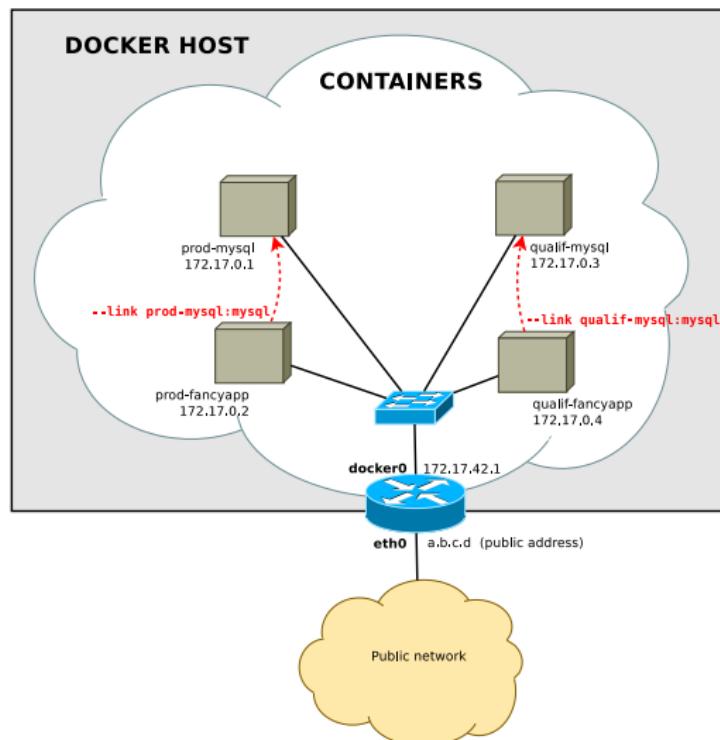

```
docker run --link ctr:alias ...
```

→ container *ctr* will be known as *alias* inside the new container

```
$ docker run --name my-server debian sh -c 'hostname -i && sleep 500' &  
172.17.0.4  
  
$ docker run --rm -t -i --link my-server:srv debian  
root@d752180421cc:/# ping srv  
PING srv (172.17.0.4): 56 data bytes  
64 bytes from 172.17.0.4: icmp_seq=0 ttl=64 time=0.195 ms
```

<sup>7</sup>since v1.9.0, links are superseded by user-defined networks

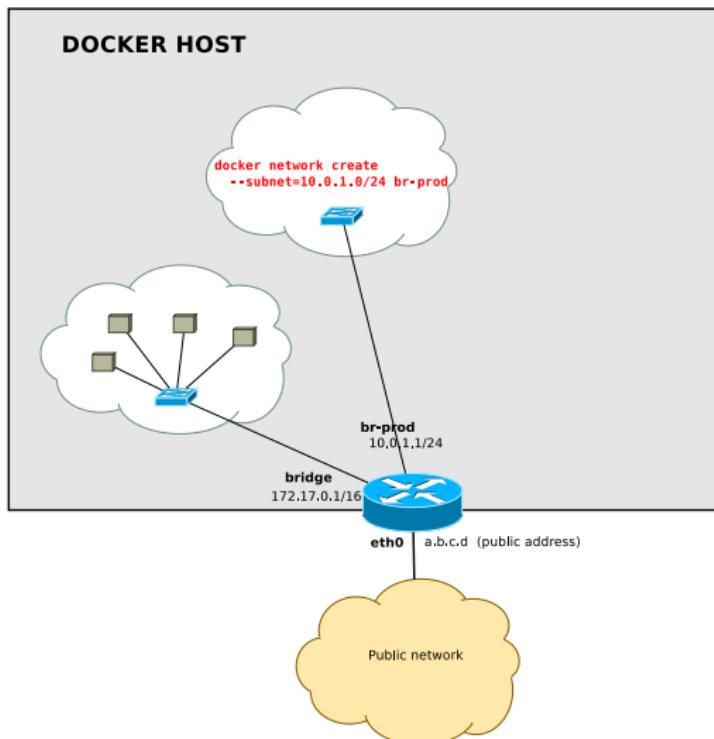

# Link Example

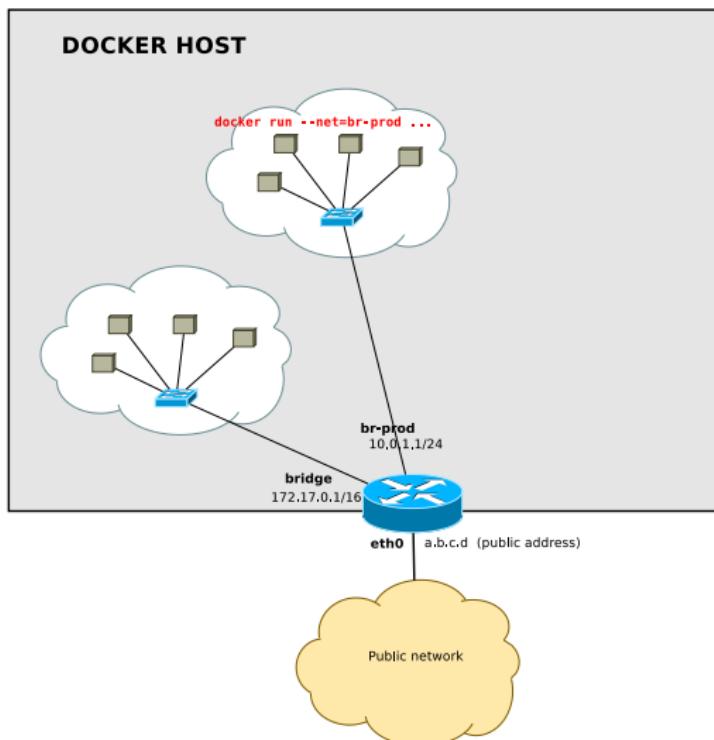

## User-defined networks (since v1.9.0)

- by default new containers are connected to the main network (named “bridge”, 172.17.0.0/16)
- the user can create additional networks:  
`docker network create NETWORK`
- newly created containers are connected to one network:  
`docker run --net=NETWORK`
- container may be dynamically attached/detached to any network:  
`docker network connect NETWORK CONTAINER`  
`docker network disconnect NETWORK CONTAINER`
- networks are isolated from each other, communications is possible by attaching a container to multiple networks

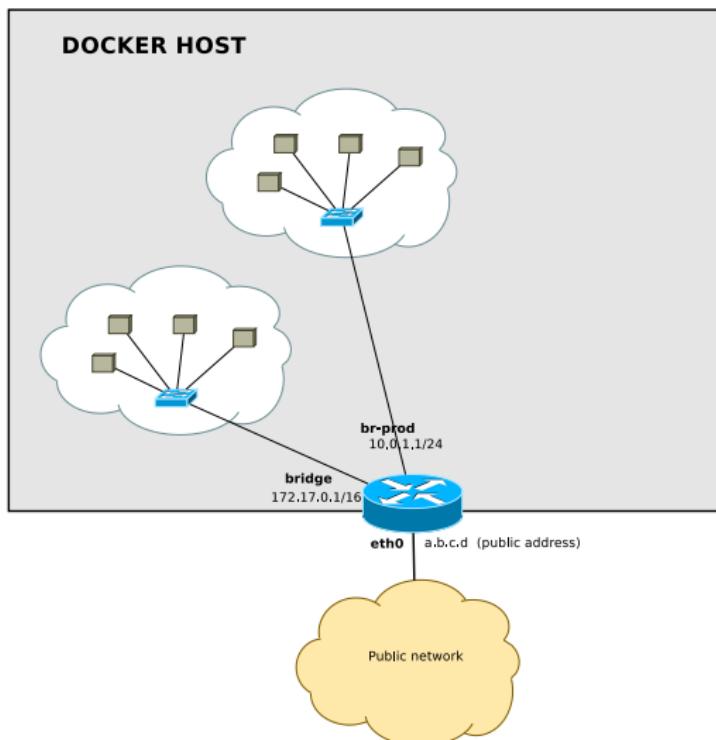

# User-defined networks example

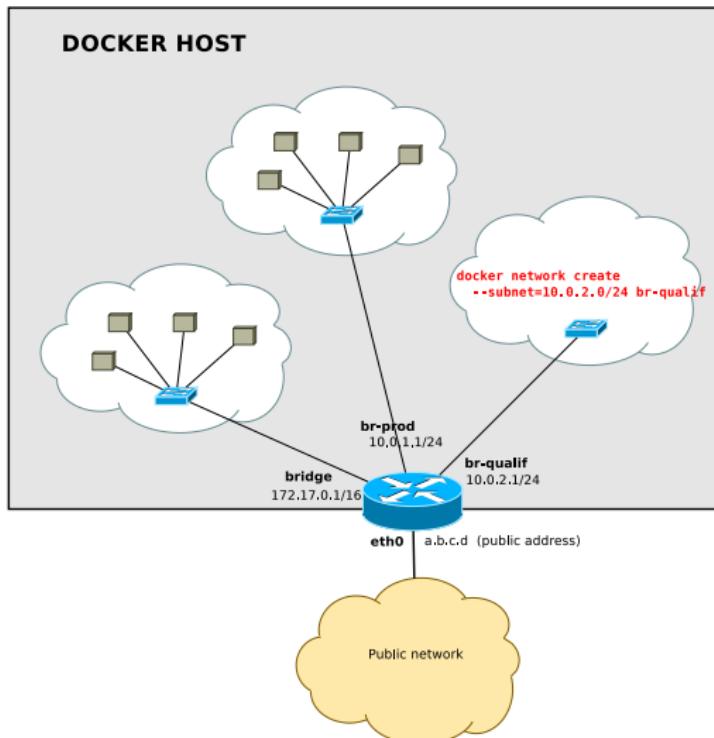

# User-defined networks example

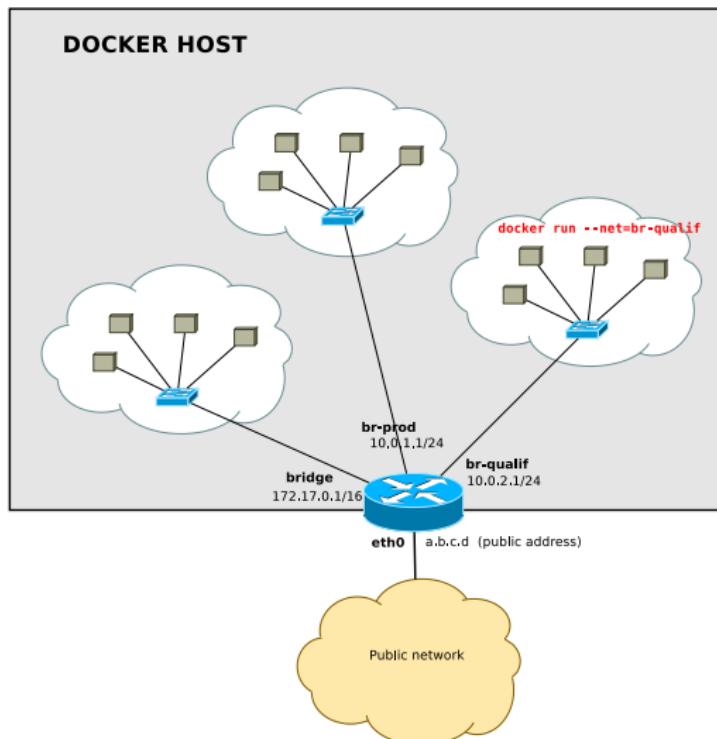

# User-defined networks example

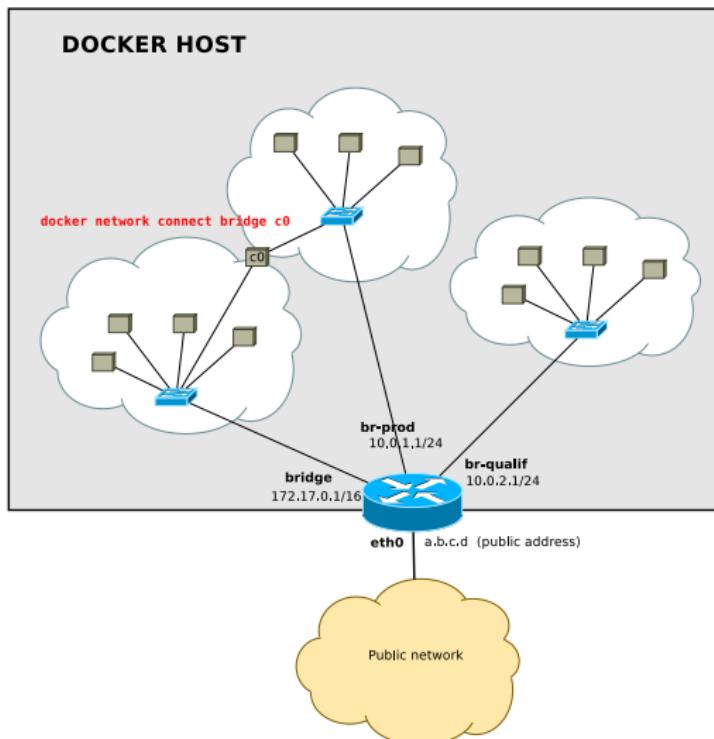

# User-defined networks example

# User-defined networks example

# User-defined networks example

## docker run — publish a TCP port

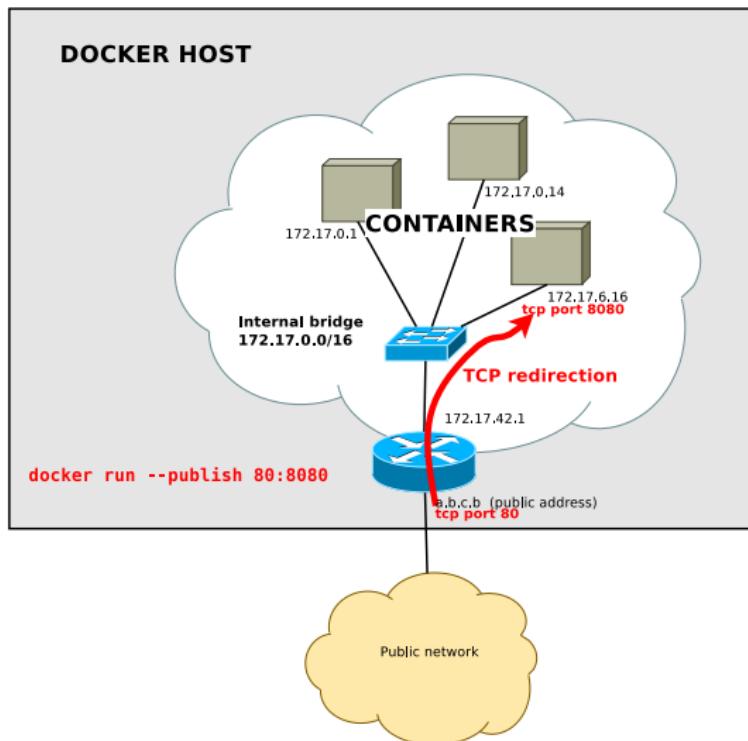

Containers are deployed in a private network, they are not reachable from the outside (unless a redirection is set up)

```
docker run -p [ipaddr:]hostport:containerport
```

→ redirect incoming connections to the TCP port *hostport* of the host to the TCP port *containerport* of the container

The listening socket binds to 0.0.0.0 (all interfaces) by default or to *ipaddr* if given

# publish example

# publish example

## bind to all host addresses

```
$ docker run -d -p 80:80 nginx
52c9105e1520980d49ed00ecf5f0ca694d177d77ac9d003b9c0b840db9a70d62

$ wget -nv http://localhost/
2016-01-12 18:32:52 URL:http://localhost/ [612/612] -> "index.html" [1]
$ wget -nv http://172.17.42.1/
2016-01-12 18:33:14 URL:http://172.17.42.1/ [612/612] -> "index.html" [1]
```

## bind to 127.0.0.1

```
$ docker run -d -p 127.0.0.1:80:80 nginx
4541b43313b51d50c4dc2722e741df6364c5ff50ab81b828456ca55c829e732c

$ wget -nv http://localhost/
2016-01-12 18:37:10 URL:http://localhost/ [612/612] -> "index.html.1" [1]
$ wget http://172.17.42.1/
--2016-01-12 18:38:32-- http://172.17.42.1/
Connecting to 172.17.42.1:80... failed: Connection refused.

# Part 4.

# Managing docker images

## Docker images

A docker image is a snapshot of the filesystem + some metadata

- immutable
- copy-on-write storage
  - for instantiating containers
  - for creating new versions of the image (multiple layers)
- identified by a unique hex ID (hashed from the image content)
- may be tagged<sup>8</sup> with a human-friendly name
  - eg: `debian:wheezy` `debian:jessie` `debian:latest`

---

<sup>8</sup>possibly multiple times

# Image management commands

command	description
<code>docker images</code>	list all local images
<code>docker history image</code>	show the image history (list of ancestors)
<code>docker inspect image...</code>	show low-level infos (in json format)
<code>docker tag image tag</code>	tag an image

# Images vs. Layers

**docker < v1.10**  
**no distinction between images & layers**

**docker >= v1.10**  
**layers are hidden to the user**  
**(implementation detail)**

## Image tags

A docker tag is made of two parts: “*REPOSITORY: TAG*”

The *TAG* part identifies the version of the image. If not provided, the default is “`:latest`”

```
$ docker images
```

REPOSITORY	TAG	IMAGE ID	CREATED	VIRTUAL SIZE
debian	8	835c4d274060	2 weeks ago	122.6 MB
debian	8.0	835c4d274060	2 weeks ago	122.6 MB
debian	jessie	835c4d274060	2 weeks ago	122.6 MB
debian	rc-buggy	350a74df81b1	7 months ago	159.9 MB
debian	experimental	36d6c9c7df4c	7 months ago	159.9 MB
debian	6.0.9	3b36e4176538	7 months ago	112.4 MB
debian	squeeze	3b36e4176538	7 months ago	112.4 MB
debian	wheezy	667250f9a437	7 months ago	115 MB
debian	latest	667250f9a437	7 months ago	115 MB
debian	7.5	667250f9a437	7 months ago	115 MB
debian	unstable	24a4621560e4	7 months ago	123.6 MB
debian	testing	7f5d8ca9fdcf	7 months ago	121.8 MB
debian	stable	caa04aa09d69	7 months ago	115 MB
debian	sid	f3d4759f77a7	7 months ago	123.6 MB
debian	7.4	e565fbcc6033	9 months ago	115 MB
debian	7.3	b5fe16f2ccba	11 months ago	117.8 MB

## Tagging conventions (1/2)

Local tags may have arbitrary names, however the `docker push` and `docker pull` commands expect some conventions

The *REPOSITORY* identifies the origin of the image, it may be:

- a name (eg: `debian`)
  - refers to a repository on the official registry
  - <https://registry.hub.docker.com/>
- a hostname+name (eg: `some.server.com/repo`)
  - refers to an arbitrary server supporting the registry API
  - [https://docs.docker.com/reference/api/registry\\_api/](https://docs.docker.com/reference/api/registry_api/)

## Tagging conventions (2/2)

Use slashes to delimit namespaces (for subprojects):

<b>image name</b>	<b>description</b>
debian	(semi-)official debian images
fedora	official fedora images
fedora/apache	apache images provided by the fedora project
fedora/couchdb	couchdb images provided by the fedora project

# Image transfer commands

## Using the registry API

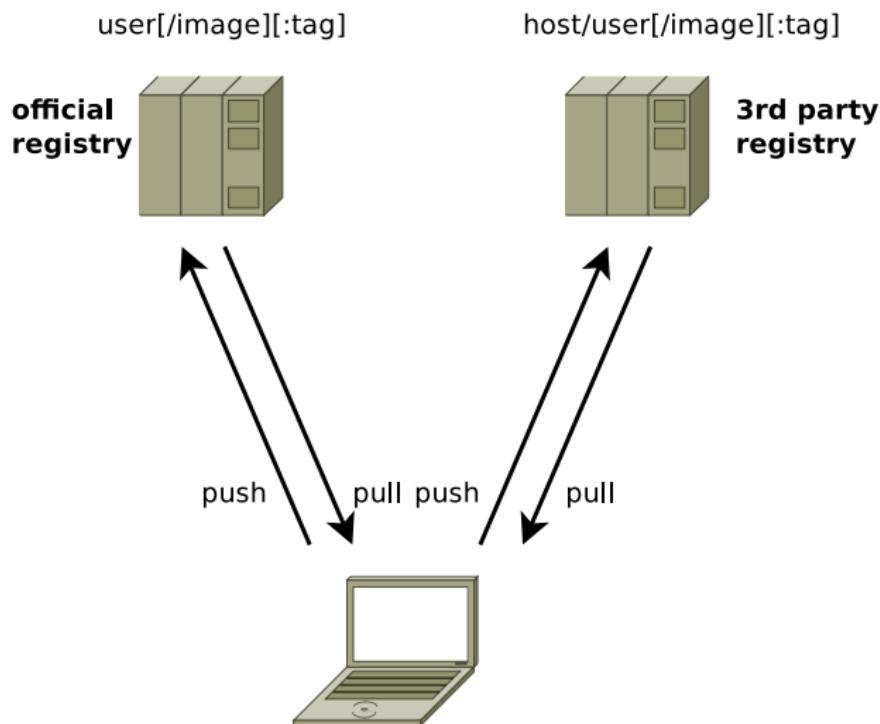

<code>docker pull repo[:tag]...</code>	pull an image/repo from a registry
<code>docker push repo[:tag]...</code>	push an image/repo from a registry
<code>docker search text</code>	search an image on the official registry
<code>docker login ...</code>	login to a registry
<code>docker logout ...</code>	logout from a registry

## Manual transfer

<code>docker save repo[:tag]...</code>	export an image/repo as a tarball
<code>docker load</code>	load images from a tarball
<code>docker-ssh<sup>9</sup> ...</code>	proposed script to transfer images between two daemons over ssh

# Part 5.

# Docker builder

# What is the Docker builder ?

Docker's builder relies on

- a DSL describing how to build an image
- a cache for storing previous builds and have quick iterations

The builder input is a **context**, i.e. a directory containing:

- a file named Dockerfile which describe how to build the container
- possibly other files to be used during the build

## Build an image

```
docker build [ -t tag ] path
```

→ build an image from the context located at *path* and optionally tag it as *tag*

The command:

1. makes a tarball from the content<sup>10</sup> of *path*
2. uploads the tarball to the docker daemon which will:
  - 2.1 execute the content of Dockerfile, committing an intermediate image **after each** command
  - 2.2 (if requested) tag the final image as *tag*

---

<sup>10</sup>unwanted files may be excluded if they match patterns listed in `.dockerignore`

# Dockerfile example

```
# base image: last debian release
FROM debian:wheezy

# name of the maintainer of this image
MAINTAINER Anthony.Baire@irisa.fr

# install the latest upgrades
RUN apt-get update && apt-get -y dist-upgrade

# install nginx
RUN apt-get -y install nginx

# set the default container command
# -> run nginx in the foreground
CMD ["nginx", "-g", "daemon off;"]

# Tell the docker engine that there will be something listening on the tcp port 80
EXPOSE 80
```

## Dockerfile format

<https://docs.docker.com/reference/builder/>

- comments start with “#”
- commands fit on a single line  
(possibly *continuated with \*)
- first command must be a FROM  
(indicates the parent image or scratch to start from scratch)

## Builder main commands

command	description
<code>FROM image scratch</code>	base image for the build
<code>MAINTAINER email</code>	name of the mainainer (metadata)
<code>COPY path dst</code>	copy <i>path</i> from the context into the container at location <i>dst</i>
<code>ADD src dst</code>	same as <code>COPY</code> but untar archives and accepts http urls
<code>RUN args...</code>	run an arbitrary command inside the container
<code>USER name</code>	set the default username
<code>WORKDIR path</code>	set the default working directory
<code>CMD args...</code>	set the default command
<code>ENV name value</code>	set an environment variable

## Builder cache

Each layer created by the builder is fingerprinted according to:

- the ID of the previous image
- the command and its arguments
- the content of the imported files (for `ADD` and `COPY`)

 `RUN`'s side-effects are not fingerprinted

When rebuilding an image docker will reuse a previous image if its fingerprint is the same

# Part 6.

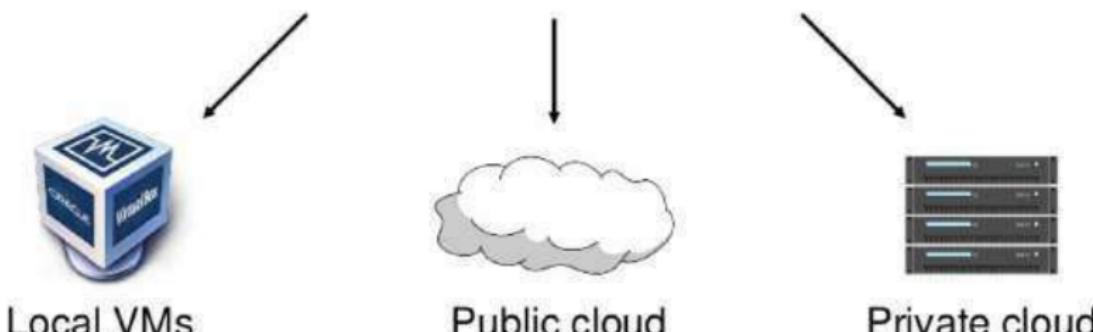

# Orchestration

- Docker Machine
- Docker Swarm
- Docker Compose
- other tools

# Docker Machine

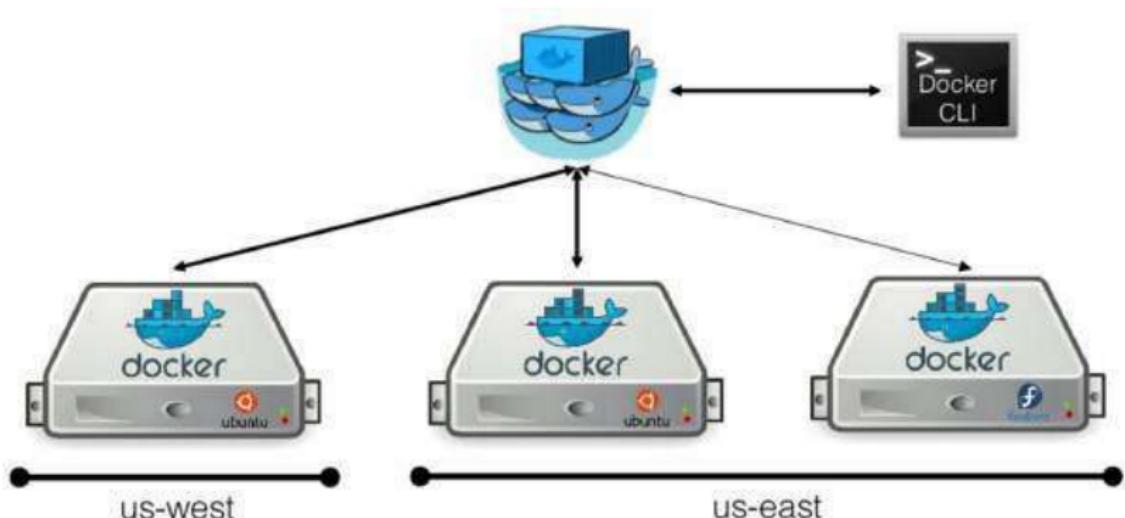

abstraction for provisionning and using docker hosts

```
$ machine create
```

# Docker Swarm

manage a cluster of docker hosts

# Docker Compose

manage a collection of containers

```
group.yml
```

```
name: counter

containers:
  web:
    build: .
    command: python app.py
    ports:
      - "5000:5000"
    volumes:
      - .:/code
    links:
      - redis
  redis:
    image: redis:latest
```

## Other tools

Not an exhaustive list

- Shipyard
- Kubernetes (Google)
- Fleet (CoreOS)

# Part 7.

# Security

- host/container isolation
- container/container isolation
- other security considerations

## Security options

### Container/Host isolation

- run the daemon inside a VM
- run the container as a normal user (`docker run -u`)
- reduce root privileges
  - capabilities (since v1.2)
  - seccomp (since v1.10)
  - AppArmor/SELinux
- mount all container filesystems with `-o nosuid`
- use a user namespace (since v1.10)

### Container/Container isolation

- disable intercontainer communications (`--icc=false`)
- isolate containers in different networks

## Running containers as normal user

```
docker run -u USER ...
```

should be safe, but... beware of

- setuid executables in the docker image  
→ *mount /var/lib/docker with '-o nosuid'*
- setuid executables in external volumes  
→ *mount all data volumes with '-o nosuid'*
- /etc/passwd in the docker image  
→ *use numeric ids: (docker run -u UID:GID)*

## Reduced root capabilities

- kernel capabilities supported since v1.2
- containers use a default set limited to 14 capabilities<sup>11</sup>:

AUDIT_WRITE	CHOWN	NET_RAW	SETPCAP
DAC_OVERRIDE	FSETID	SETGID	KILL
NET_BIND_SERVICE	FOWNER	SETUID	
SYS_CHROOT	MKNOD	SETFCAP	
- add additional capabilities: `docker run --cap-add=XXXXXX ...`
- drop unnecessary capabilities: `docker run --cap-drop=XXXXXX ...`  
→ should use `--cap-drop=all` for most containers

```
$ docker run --rm -t -i debian
root@04223cbb1334:/# ip addr replace 172.17.0.42/16 dev eth0
RTNETLINK answers: Operation not permitted
root@04223cbb1334:/# exit

$ docker run --rm -t -i --cap-add NET_ADMIN debian
root@9bf2a570a6a6:/# ip addr replace 172.17.0.42/16 dev eth0
root@9bf2a570a6a6:/#
```

<sup>11</sup>over the 38 capabilities defined in the kernel (man 7 capabilities)

## Reduced syscall whitelist

seccomp-bpf == fine-grained access control to kernel syscalls

- enabled by default since v1.10
- default built-in profile<sup>12</sup> whitelists only harmless syscalls<sup>13</sup>
- alternative configs:
  - disable seccomp (`--security-opt=seccomp:unconfined`)
  - provide a customised profile (derived from the default<sup>14</sup>)

```
$ docker run --rm debian date -s 2016-01-01
date: cannot set date: Operation not permitted
$ docker run --rm --cap-add sys_time debian date -s 2016-01-01
date: cannot set date: Operation not permitted
$ docker run --rm --security-opt seccomp:unconfined debian date -s 2016-01-01
date: cannot set date: Operation not permitted
$ docker run --rm --cap-add sys_time --security-opt seccomp:unconfined debian date -s 2016-01-01
Fri Jan 1 00:00:00 UTC 2016
```

<sup>12</sup> <https://docs.docker.com/engine/security/seccomp/>

<sup>13</sup> harmful means everything that deals with administration (eg: set time) or debugging (eg: ptrace)

<sup>14</sup> <https://github.com/docker/docker/blob/master/profiles/seccomp/default.json>

## User namespaces

since v1.10 but not enabled by default

- UIDs/GIDs inside the containers mapped to another range outside the container
- useful for:
  - preventing fs-based attacks (*e.g.: root user inside the container creates a setuid executable in an external volume*)
  - isolating docker users from each other (*one docker daemon for each user, with uids remapped to different ranges*)
- limits (as of v1.10)
  - global config only (daemon scope)
  - coarse mapping only (hardcoded range: 0..65535)

## Container/Container isolation

By default all containers can connect to any other container (located in the same bridge)

Mitigations:

- run the daemon with **--icc=false**
  - all communications filtered by default
  - whitelist-based access with **--link**  
*(only EXPOSEd ports will be whitelisted)*
- attach containers to different networks

## Other security considerations

- images are immutable
  - need a process to apply automatic security upgrades, e.g:
    - apply upgrades & commit a new image
    - regenerate the image from the Dockerfile
- docker engine control == root on the host machine
  - give access to the docker socket only to trusted users
- avoid `docker run --privileged` (gives full root access)
- avoid the insecure v1 registry API (for `push/pull`)
  - run the daemon with `--insecure-registry=false --disable-legacy-registry`
- collisions on image IDs (no longer possible since v1.10)
